IMalive App

GitHub Username:AhmedAlghoul

IMalive

Description

IMalive lets the people you care about know that you're alive.
Schedule specific messages to specific people on specific days at specific times. When the time comes, IMalive will send you a notification asking if you are indeed alive. When you confirm your aliveness, the app will send your message to the recipient.

1-the App keeps all strings in a strings.xml file and enables RTL layout switching on all layouts.

2- App integrates two Google services , Admob and Firebase.

3- storing data using SQLite

App utilizes stable release versions of all libraries, Gradle, and Android Studio.

Intended User

The intended user for Still Alive is anyone who wants to let people who worry about them know they are okay. For example, students who just left for college who have moms that message them every day and ask if they are okay.

Features

List the main features of your app. For example:

- Pick a contact from your phone's address book
- Configure days and time for a specified message to be sent to the selected contact
- Easily manage existing configured messages
    - Toggle on and off scheduled messages
    - Update configuration or delete entirely

User Interface Mocks

Main Screen - Messages Dashboard

The main screen is a dashboard where users can manage existing messages they have configured, as well as create and configure new messages.

Message Composer Screen

The message composer screen lets users specify a date and time as well as a message to be delivered to the selected contact.

Widget

Widget allows user to see and edit reminders directly from the home screen.

Key Considerations

How will your app handle data persistence?

The app will use a 3rd-party library to persist simple data.

Describe any corner cases in the UX.

Since the app will use alarms for scheduling push notifications, the alarms will need to be rescheduled if the user restarts their device.

Describe any libraries you'll be using and share your reasoning for including them.

I'll be using Realm.io for the database to store and retrieve data created within the app. I choose Realm because it makes implementing a SQLite database fast and easy.

Next Steps: Required Tasks

This is the section where you can take the main features of your app (declared above) and decompose them into tangible technical tasks that you can complete incrementally until you have a finished app.

Task 1: Project Setup(using Java)

Before I begin developing my app, I'll first need to add Realm as a dependency in my app's build.gradle file. Once I have Realm available, I'll be able to save and retrieve the data users will be creating in the app.

Task 2: Implement UI for Each Activity and Fragment

- Build UI for MainActivity
    - Implement FloatingActionButton which starts an intent to the default contacts picker when clicked
    - Implement ListView that displays the scheduled messages users created via the MessageComposerActivity
- Build UI for MessageComposerActivity
    - Implement UI control to select one or many days of the week
    - Implement UI control to select a time
    - Implement EditTextView for the user to type a message
    - Schedule alarms with AlarmManager for the date set by the user so a push notification can be sent

Task 3: Handle Corner Case

If the device is restarted, the scheduled alarms must be rescheduled so that users can be notified via push notification to confirm their aliveness. I will register a receiver in the manifest to listen for when the phone is rebooted to achieve this.

Stage 2 – Build: Overview

In the second stage, app widget is added to the project and also the location services and admob is also implemented. App uses internet to access admob and also location services are accessed through GPS, mobile network or WiFi. Uses location API but only when specified by the user. Addition of content provider + loader to access phone contacts, set reminders etc. IntentService will be used to make network calls and users will be able to share their location.
